Physician Validation Form

New Cases

Previous Version
Lichen planus (LP) remains a polymorphic inflammatory condition, classically described by the 6 P's (Pruitic, Planar, Purple, Polygonal Papules and Plaques), but its presentation is highly variable. Cutaneous manifestations span discrete, well-defined papules often favoring flexural areas or extremities, to confluent, irregular plaques sometimes mimicking eczematous or psoriatic processes. Color ranges from violaceous to erythematous/salmon, and even hyperpigmented brown/gray,

Current Version
Lichen planus (LP) presents a protean morphology, challenging clinicians despite its classic description. While the '6 P's' offer a mnemonic, the reality spans discrete, erythematous to violaceous papules often found on extremities like the hands or trunk, to confluent, scaly plaques potentially mimicking psoriasis or eczema. Lesions can be planar or dome-shaped, smooth or scaly, and color varies widely from pink/salmon to violaceous (implied by 'purple'), or even hyperpigmented brown/gray, especially in darker skin or during resolution.

Rigorouslyness of Medical Logic

☐ Irrational ☐ Less Rational ☐ Neutral ☐ Partially Rational ☐ Rational
